

Chapter 1

Automatic Model Description

“When I write, I feel like an armless, legless man with a crayon in his mouth.”

– *Kurt Vonnegut*

The previous chapter showed how to automatically build structured models through a language of kernels, how to decompose the resulting models into the different types of structure present, and how to visually illustrate the type of structure captured by each component. This chapter will show how to automatically describe the resulting model structures with English text.

Most of the structure present in each component was determined by that component’s kernel. Even across different datasets, the meaning of the individual parts of those kernels is relatively consistent. For example, *Per* usually indicates some sort of repeating structure, and *SE* usually indicates smooth change over time. This chapter shows how to take advantage of this modularity to develop a method for automatically describing the structure represented by components of structured GP models through text. The main idea is to treat every component of a product kernel as an adjective, or as a short phrase which modifies the description of a kernel.

Combining model search, plots, and text, we present a system which automatically generates reports which highlight interpretable features discovered in a variety of data sets. An example of a complete automatically-generated report can be found in ??.

The work appearing in this chapter was written in collaboration with James Robert Lloyd, Roger Grosse, Joshua B. Tenenbaum, Zoubin Ghahramani, and was published in (Lloyd et al., 2014). The procedure translating kernels into adjectives grew out of discussions between James and myself. James Lloyd wrote the code to automatically generate reports, and ran all of the experiments.

1.1 Generating Descriptions of Kernels

There are two main features of our language of GP models that allow description to be performed automatically. First, the sometimes complicated kernel expressions found by the model search can always be simplified into a sum of products. As discussed in section 1.4, a sum of kernels corresponds to a sum of functions, so each product can be described separately. Second, each kernel in a product modifies the resulting model in a consistent way. Therefore, to generate a description of a product of kernels, we can describe one kernel using a noun with all others described using adjectives.

For example, we can describe the product of kernels $\text{Per} \times \text{SE}$ by representing Per by a noun (“a periodic function”) modified by a phrase representing the effect of the SE kernel (“whose shape varies smoothly over time”). To simplify the system, we restrict the base kernels to C , Lin , WN , SE , Per , and σ (allowing changepoints and change-windows).

1.1.1 Simplification Rules

In order to be able to use the same adjectives to for each type of kernel in different circumstances, we must convert each kernel expression into a standard, simplified form.

We do this by first distributing all products of sums into a sum of products. Then, we apply several simplifications to the kernel expression:

- Products of two or more SE kernels can be equivalently represented by a single SE with different parameters.
- Multiplying the white-noise kernel WN by any stationary kernel (C , WN , SE , or Per) gives another WN kernel.
- Multiplying any kernel by C only changes the parameters of the original kernel, and so can be factored out of any product in which it appears.

After applying these rules, any kernel can be written as a sum of terms of the form:

$$K \prod_m \text{Lin}^{(m)} \prod_n \sigma^{(n)}, \quad (1.1)$$

where K is one of $\{\text{WN}, \text{C}, \text{SE}, \prod_k \text{Per}^{(k)}\}$ or $\{\text{SE} \prod_k \text{Per}^{(k)}\}$, where $\prod_i k^{(i)}$ denotes a product of kernels, each with different parameters. We use superscripts to distinguish between different instances of the same kernel appearing in a product: $\text{SE}^{(1)}$ can have different kernel parameters than $\text{SE}^{(2)}$.

1.1.2 Describing Each Kernel in a Product

Loosely speaking, each kernel in a product modifies the resulting GP model in a consistent way. This allows us to describe the contribution of each kernel in a product as an adjective, or more generally as a post-modifier of a noun. We now describe how each of the kernels in our grammar modifies a GP model.

- **Multiplication by SE** removes long range correlations from a model since, $\text{SE}(x, x')$ decreases monotonically to 0 as $|x - x'|$ increases. This will convert any global correlation structure into local correlation only.
- **Multiplication by Lin** is equivalent to multiplying the function being modeled by a linear function. If $f(x) \sim \text{GP}(0, k)$, then $xf(x) \sim \text{GP}(0, \text{Lin} \times k)$. This causes the standard deviation of the model to vary linearly without affecting the correlation.
- **Multiplication by σ** is equivalent to multiplying the function being modeled by a sigmoid, which means that the function goes to zero before or after some point.
- **Multiplication by Per** modifies the correlation structure in the same way as multiplying the function by an independent periodic function. This follows from the fact that if $f_1(x) \sim \text{GP}(0, k_1)$ and $f_2(x) \sim \text{GP}(0, k_2)$ then

$$\text{Cov}[f_1(x)f_2(x), f_1(x')f_2(x')] = k_1(x, x')k_2(x, x'). \quad (1.2)$$

Put more plainly, a GP whose covariance is a product of kernels has the same covariance (but not necessarily the same higher moments) as a product of two functions, each drawn from the corresponding GP prior. This identity holds for any two kernels, and can be used to generate a cumbersome “worst-case” description in cases where a more meaningful description of the effect of a kernel is not obvious.

Table 1.1 gives the corresponding description of the effect of adding each type of kernel to a product, written as a post-modifier. Table 1.2 gives the corresponding description of each kernel before it has been multiplied by any other, written as a noun phrase.

1.1.3 Combining Descriptions into Noun Phrases

In order to build a noun phrase describing a product of kernels, we can choose one kernel to act as a head noun, which is then modified by appending descriptions of the other

| Kernel | Postmodifier phrase |
|----------------------------|---|
| SE | whose shape changes smoothly |
| Per | modulated by a periodic function |
| Lin | with linearly varying amplitude |
| $\prod_k \text{Lin}^{(k)}$ | with polynomially varying amplitude |
| $\prod_k \sigma^{(k)}$ | which applies until / from [changeoint] |

Table 1.1 Descriptions of the effect of each kernel, written as a post-modifier.

| Kernel | Noun phrase |
|----------------------------|--------------------|
| WN | uncorrelated noise |
| C | constant |
| SE | smooth function |
| Per | periodic function |
| Lin | linear function |
| $\prod_k \text{Lin}^{(k)}$ | polynomial |

Table 1.2 Noun phrase descriptions of each type of kernel

kernels in the product.

As an example, a kernel of the form $\text{Per} \times \text{Lin} \times \sigma$ could be described as a

$$\underbrace{\text{Per}}_{\text{periodic function}} \times \underbrace{\text{Lin}}_{\text{with linearly varying amplitude}} \times \underbrace{\sigma}_{\text{which applies until 1700.}}$$

where Per was chosen to be the head noun. The head noun is chosen according to the following ordering:

$$\text{Per, WN, SE, C, } \prod_m \text{Lin}^{(m)}, \prod_n \sigma^{(n)} \quad (1.3)$$

Combining tables 1.1 and 1.2 and equation (1.3) provides a general method to produce descriptions of kernels.

Extensions

In practice, we also incorporate a number of other rules which help to make the descriptions shorter, easier to parse, or clearer:

- We add extra adjectives depending on kernel parameters. For example, an SE with a relatively short lengthscale might be described as “a rapidly-varying smooth

function”.

- Descriptions can include kernel parameters. For example, we might write that a function is “repeating with a period of 7 days”.
- Descriptions can include extra information about the model not contained in the kernel. For example, based on the slope of the posterior mean, we might “a linearly increasing function”.
- Some kernels can be described through pre-modifiers. For example, we might write “an approximately periodic function” as opposed to “a periodic function whose shape changes smoothly”.

Ordering additive components

The reports generated by ABCD attempt to present the most interesting or important features of a data set first. As a heuristic, we order components by always adding next the component which most reduces the 10-fold cross-validated mean absolute error.

1.1.4 Worked Example

Suppose we start with a kernel of the form

$$SE \times (WN \times Lin + CP(C, Per)). \quad (1.4)$$

This is converted to a sum of products:

$$SE \times WN \times Lin + SE \times C \times \sigma + SE \times Per \times \bar{\sigma}. \quad (1.5)$$

which is simplified to

$$WN \times Lin + SE \times \sigma + SE \times Per \times \bar{\sigma}. \quad (1.6)$$

To describe the first component, the head noun description for WN, “uncorrelated noise”, is concatenated with a modifier for Lin, “with linearly increasing standard deviation”. The second component is described as “A smooth function with a lengthscale of [lengthscale] [units]”, corresponding to the SE, “which applies until [changepoint]”, which corresponds to the σ . Finally, the third component is described as “An approximately periodic function with a period of [period] [units] which applies from [changepoint]”.

1.2 Example Descriptions

In this section, we demonstrate the ability of our procedure to write intelligible descriptions of the structure present in two time series. The model descriptions were generated based off of models produced by the automatic search method presented in section 1.4.

1.2.1 Summarizing 400 Years of Solar Activity

First, we show excerpts from the report automatically generated on annual solar irradiation data from 1610 to 2011. This dataset is shown in figure 1.1.

Fig. 1.1 Solar irradiance data.

This time series has two pertinent features: a roughly 11-year cycle of solar activity, and a period lasting from 1645 to 1715 with much smaller variance than the rest of the dataset. This flat region corresponds to the Maunder minimum, a period in which sunspots were extremely rare ([Lean et al., 1995](#)). The Maunder minimum is an example of the type of structure which can be captured by changewindows. ABCD clearly identifies these two features, as discussed below.

- A constant.
- A constant. This function applies from 1643 until 1716.
- A smooth function. This function applies until 1643 and from 1716 onwards.
- An approximately periodic function with a period of 10.8 years. This function applies until 1643 and from 1716 onwards.

Fig. 1.2 Automatically generated descriptions of the first four components discovered by ABCD on the solar irradiance data set. The dataset has been decomposed into diverse structures with simple descriptions.

Figure 1.2 show plots and natural-language summaries of the top four components discovered by ABCD. From these short summaries, we can see that the system has identified the Maunder minimum (second component) and 11-year solar cycle (fourth component). These components are visualized and described in figures 1.3 and 1.5, respectively. The third component, visualized in figure 1.4, captures long-term trends.

Fig. 1.3 One of the learned components corresponds to the Maunder minimum.

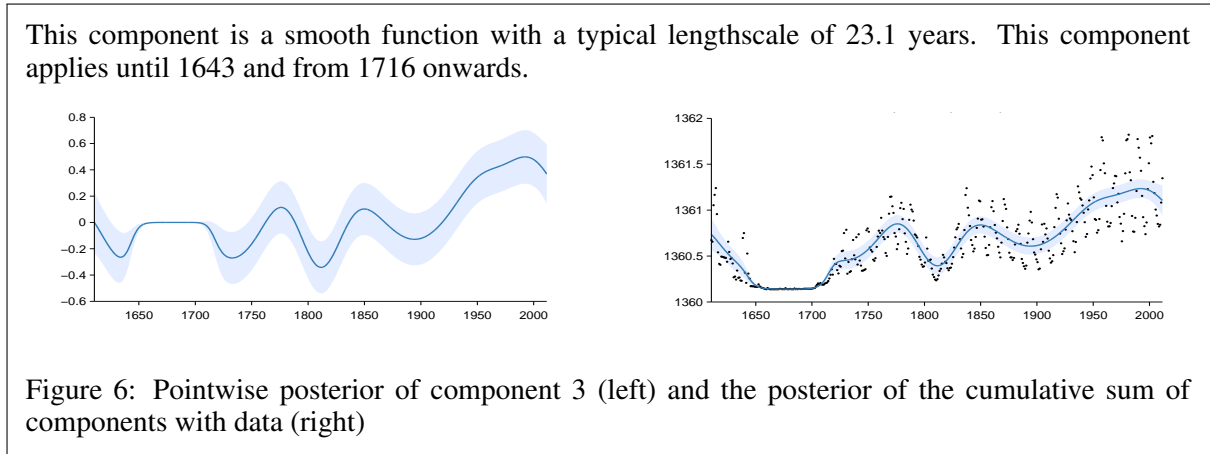

Fig. 1.4 Characterizing the medium-term smoothness of solar activity levels. By allowing other components to explain the periodicity, noise, and the Maunder minimum, ABCD can isolate the part of the signal best explained by a slowly-varying trend.

The complete report generated on this dataset can be found in ??.

This component is approximately periodic with a period of 10.8 years. Across periods the shape of this function varies smoothly with a typical lengthscale of 36.9 years. The shape of this function within each period is very smooth and resembles a sinusoid. This component applies until 1643 and from 1716 onwards.

Figure 8: Pointwise posterior of component 4 (left) and the posterior of the cumulative sum of components with data (right)

Fig. 1.5 Extract from an automatically-generated report describing the model components discovered by automatic model search. This part of the report isolates and describes the approximately 11-year sunspot cycle, also noting its disappearance during the 16th century, a time known as the Maunder minimum (Lean et al., 1995).

1.2.2 Describing Changing Noise Levels

Next, we present excerpts of the description generated by our procedure on international airline passenger data. The model being described is the same as that shown in ??.

High-level descriptions of the four components discovered are shown in figure 1.6.

- A linearly increasing function.
- An approximately periodic function with a period of 1.0 years and with linearly increasing amplitude.
- A smooth function.
- Uncorrelated noise with linearly increasing standard deviation.

Fig. 1.6 Short descriptions and summary statistics for the four components of the airline model.

The second component, shown in figure 1.7, is accurately described as approximately (SE) periodic (Per) with linearly growing amplitude (Lin). By multiplying a white noise kernel by a linear kernel, the model is able to express heteroscedasticity (covariance which changes over time). This component is described in figure 1.8.

The complete report generated on this dataset can be found in the supplementary material of (Lloyd et al., 2014). Other example reports describing a wide variety of

This component is approximately periodic with a period of 1.0 years and varying amplitude. Across periods the shape of this function varies very smoothly. The amplitude of the function increases linearly. The shape of this function within each period has a typical lengthscale of 6.0 weeks.

Figure 4: Pointwise posterior of component 2 (left) and the posterior of the cumulative sum of components with data (right)

Fig. 1.7 Capturing non-stationary periodicity in the airline data

This component models uncorrelated noise. The standard deviation of the noise increases linearly.

Figure 8: Pointwise posterior of component 4 (left) and the posterior of the cumulative sum of components with data (right)

Fig. 1.8 Modeling time-changing variance in the airline dataset.

time-series can be found at mlg.eng.cam.ac.uk/Lloyd/abcdoutput/

1.3 Related Work

To the best of our knowledge, our procedure is the first example of automatic description of nonparametric statistical models. However, systems with natural language output have been built in the areas of video interpretation (Barbu et al., 2012) and automated theorem proving (Ganesalingam and Gowers, 2013).

Source Code

Source code to perform all experiments is available at github.com/jamesrobertlloyd/gpss-research.

1.4 Conclusion

Towards the goal of automating statistical modeling we have presented a system which, given a structured GP model, automatically generates detailed reports that describe patterns in the data captured by the model. Combined with the automatic model-search of section 1.4 gives a procedure which can discover and describe a variety of patterns on several time series.
